

("DCO", i.e., point at which customs processing in the destination country is completed); or the supplier shipping dock ("SSD").

[0003] Existing supplier performance reporting systems generally pick a single start point and a single end point to use as the standardized start and end points for determining the time period against which to measure whether or not a delivery is "on time." Such systems require users to report on time performance using a standardized start and end point. This approach has at least two disadvantages. First, the customers that are providing on-time delivery data for use by such systems may not ordinarily track delivery times using the standardized start point and end point required by the system. Thus, customers may have to adjust existing internal procedures in order to report delivery time data that is useable by such systems. A second disadvantage of such systems is that customers whose businesses place an importance on delivery times using start and end points different from those used by the reporting system will not be able to gauge the performance of suppliers in a manner that is consistent with the particular business needs of such customers.

[0004] Existing supplier performance reporting systems also typically report the percentage of orders that are returned. However, existing systems simply report "reject performance" as a percentage of total orders that are returned without distinguishing between whether the return was supplier caused or customer caused. In some contexts, it may be useful for users of a supplier performance reporting system to know how many returns were caused by the supplier and how many were caused the customer.

#### SUMMARY OF THE INVENTION

[0005] The present invention addresses some of the problems of prior supplier performance reporting systems. An aspect of a present embodiment receives and

[0013] **Figure 5** is a process diagram illustrating steps for creating a supplier performance report from Summarized Purchase Order Data.

[0014] **Figure 6** is a sample reject performance report that may be generated by the system of **Figure 1**.

[0015] **Figure 7** is a flow diagram illustrating the use of transaction data to predict whether an order reject is supplier caused or customer caused.

#### DETAILED DESCRIPTION OF THE DRAWINGS

[0016] In the following description, numerous details are set forth for purpose of explanation. However, one of ordinary skill in the art would realize that the invention may be practiced without the use of these specific details. In other instances, well-known structures and devices are shown in block diagram form in order not to obscure the description of the invention with unnecessary detail.

[0017] **Figure 1** shows a system 10 that may be used to implement the present invention. System 10 comprises one or more computers. System 10 includes at least one processing element and at least one memory storage element. The one or more computers of system 10 will have access to executable instruction code in an electronically readable medium (code and medium not separately shown). The electronically readable medium may be any medium that either stores or carries electronic signals (including signals referred to as electrical signals and signals

**[0019]** Blocks 10-1 to 10-7 and associated arrows indicate the processing and data flow of system 10. At block 10-1, data is received relevant to either basic purchase order data or summarized purchase order data (see **Figures 2a, 2b, and 3** and accompanying text) from systems 11a, 11b, and 11c. This basic or summarized data may be received through a periodic batch update process or through a persistent connection that provides real time updating of system 10's stored data. Summarized purchase order data is derived from basic purchase order data using process 30 as illustrated and described in **Figure 3** and accompanying text. That process may be performed either on subscriber system 11a, 11b, and 11c or at system 10. If process 30 is performed on a subscriber system, system 10 will receive summarized purchase order data, if process 30 is performed at block 10-1 of system 10, then system 10 will

**[0020]** A subscriber may transmit requests to system 10 through web-portal 12. Requests are received at block 10-7. At block 10-5, a response to the user request is generated. This generation of a response involves requesting and retrieving information from data storage block 10-3 as indicated by the arrows between blocks 10-5 and 10-3, and involves performing the processing necessary to generate a suitable data view for display. At block 10-6, the response is returned to the user through web-portal 12.

6

"Supplier Name", 20F-15 is labeled "Buyer Name", and the intervening fields are labeled as indicated, e.g., "Start Point" field 20F-2, "End Point" field 20F-3, etc.).

**[0022]** **Figure 2b** shows Summarized Purchase Order Data ("Summary Data") 25 derived from Basic Data 20. Summary Data 25 includes records 25R-1, 25R-2, and 25R-3 (values 1-3 in the field labeled "Record No.") and the following fields: "Record No." field 25F-1, "Supplier Name" field 25F-2, "Start Point" field 25F-3, "End Point" field 25F-4, "# of POs" (purchase orders) Field 25F-5, "# of Line Items" field 25F-6, "Orders On-Time" field 25F-7, "Line Items On-Time" field 25f-8, and "Buyer Name" field 25F-9.

**[0023]** **Figures 2a and 2b** show respective Basic and Summarized data in a single table, i.e. in a flat file format. It will be appreciated by those skilled in the art, that data may be stored in other formats such as, for example, a relational data base. Thus, Basic Data 20 may be stored in multiple tables as may Summarized Data 25. For example, alternative embodiments may store summarized data for each supplier in a separate table. Also, variations on the choice of fields will be apparent to those skilled in the art. To cite but one example, the Start Point field may be combined with the End Point field into a single start point / end point pair field without any loss in relevant information. These and other variations will be apparent to those skilled in the art and it will be understood that such variations do not depart from the spirit and scope of the present invention.

**[0024]** **Figure 3** shows an exemplary process that may be used to derive the Summary Data 25 from the Basic Data 20 of **Figure 2**. Process 30 has steps 3-1 through 3-8. In step 3-1, a Summarized Data table is created with the indicated fields. In step 3-2, subsets of data are identified in Basic Data, each record in a subset having the same supplier name, buyer name, start point, and end point. Each subset of Basic Data 20 records identified in step 3-2 corresponds to a single record in Summary Data 25 as indicated in step 3-4. Also in step 3-4, for each Summary Data

**[0026]** In step 3-5, the "# of POs" field in Summary Data 25 is populated by, for each subset identified in step 3-2, adding up the number sub-subsets identified in step 3-3, and putting the total in the record of Summary Data 25 that corresponds to the step 3-2 subset of Basic Data 20 whose step 3-3 sub-subsets were totaled. For example, Records 20R-1, 20R-2, and 20R-3 of Basic Data 20 is a subset identified in step 3-2 and thus corresponds to a record in Summary Data 25 (record 25R-1). That subset in turn has two subsets (or "sub-subsets"): (20R1, 20R2 corresponding to one purchase order number) and (20R-3 corresponding to another purchase order number). Therefore, the # of POs in record 25R-1 is 2. Of course, this step could also be phrased in terms of identifying the number of unique purchase order numbers in each subset of records identified in step 3-2.

8

identified in step 3-2. Note that since Basic Data 20 has one record for each line item number, the results of step 3-6 in this instance will simply be the number of records in each subset identified in step 3-2 (note the number "2" in the "Line Item Number" field of record 20R-2 of Basic Data 20 is an identification number, not a number of line items in that record; each record in Basic Data 20 contains a single line item). In step 3-7, the "Orders On Time" field in Summary Data 25 is populated by adding up the total number of sub-subsets identified in step 3-3 for which every record in the sub-subset has a "Received Date" value that is earlier than its "Due Date" value. In other words, an order is defined as on time if every line item in the order was delivered on time. In step 3-8, the "Line Items On Time" field in Summary Data 25 is populated by, for each corresponding step 3-2 subset, summing together all the records in which the "Received Date" is equal to or earlier than the "Due Date."

**[0028]** Those skilled in the art will recognize that process 30 represents just one example of a series of steps that might be used to convert Basic Data 20 to Summary Data 25. Also, those skilled in the art will recognized that first executable code used to carry out a first step in process 30 might be the same code as second executable code used to carry out a second step in process 30. For example, a single piece of executable code might direct a computer to, for each record in Summary Data 25, store in the "# of POs" field 25F-5, the value obtained by counting the records in Basic Data 20 that have the same the same supplier name, start point, end point, and buyer name as the corresponding Summary Data 25 record and that also have identical purchase order numbers. Such a piece of code would be performing step 3-5 of process 30, but would also implicitly be performing step 3-3 and 3-2. Thus, such a piece of code could be said to be first code for performing step 3-2, second code for performing step 3-3, and third code for performing step 3-5. Those skilled in the art will recognize therefore that executable code may be organized in a variety of ways without departing from the spirit and scope of the present invention.

**[0031]** **Figure 4** shows sample on-time performance report 40 that may be generated by the system of **Figure 1**. Report 40 includes tables 40a and 40b and reports on-time performance for a domestic supplier S1 during a reporting period. Display table 40a reports supplier S1's on time performance across all customer buyers providing data to for the system. Table 40a displays data for on time performance with respect to a plurality of start point / end point pairs. Table 40a

includes records 40aR-1, 40aR-2, 40aR-3, and 40aR-4, corresponding, respectively, to the following start point/end point pairs in field 40aF-1: OS-CFD ("order sent" - "customer final destination"), OC-SSD ("order confirmed" - "supplier shipping dock"), OC-DTO ("order confirmed" - "destination transport onboard"), OC-CFD ("order confirmed" - "customer final destination"). In addition to start point / end point field 40aF-1, table 40a also includes field 40aF-2 ("No. of orders"), field 40aF-3 ("% on time"), field 40aF-4 ("No. of line items"), and field 40aF-5 ("% on time").

**[0032]** Display table 40b reports on time performance for orders placed with supplier S1 by customer/buyer C1. Table 40b displays data for on time performance with respect to a plurality of start point / end point pairs. Table 40b includes records 40bR-1, 40bR-2, 40bR-3, and 40bR-4, corresponding to, respectively, the following indicated start point / end point pairs in field 40bF-1. In addition to start point / end point field 40bR-1, table 40b also includes field 40bF-2 ("No. of orders"), field 40bF-3 ("% on time"), field 40bF-4 ("No. of line items"), and field 40bF-5 ("% on time").

**[0033]** **Figure 5** shows an exemplary process 50 that may be used to derive displayed Supplier Report 52 from Summarized Purchase Order Data ("Summary Data") 51. Supplier Report 52 is analogous to display table 40a in **Figure 4**, in that Supplier Report 52 is indicative of on time performance for a supplier S1 based on data from all supplier S1 customers providing data to the system. Summary Data 51 is analogous to Summary Data 25 of **Figure 2b**. Process 50 has steps 5-1 through 5-8. In step 5-1, an empty Supplier Report table 52 is created with the indicated fields. In step 5-2, subsets of data are identified in Summary Data 51, each record in a subset having the same supplier name, start point, and end point. Each subset of Summary Data 51 records identified in step 5-2 corresponds to a single record in Supplier Report 52 as indicated in step 5-3. In step 5-4, for each Supplier Report 52 record created in step 5-3, the "Start point / End point" field of Supplier Report 52 is populated with the start points and end points from the corresponding subset of

Summary Data 51 records identified in step 5-2 (note, steps 5-3 and 5-4 are roughly analogous to the single step 3-2 illustrated and described in **Figure 3** and accompanying text). In step 5-5 the "No. of POs" field in Supplier Report 52 is populated by adding up the values of the number of orders in each subset of Summary Data 51 records identified in step 5-2, and putting the respective totals in the corresponding record of Supplier Report 52. In step 5-6, the "% orders on time" field of Supplier Report 52 is populated for each Supplier Report 52 record with percentages obtained by summing the orders on time values of Summary Data 51 records in the corresponding subsets identified in step 5-2, multiplying each by 100, and dividing each by the corresponding total obtained in step 5-5. In step 5-7, the "# of line items" field in Supplier Report 52 is populated by summing the number of line items value in each record of the corresponding subset identified in step 5-2. In step 5-8, the "% line items on time" field of Supplier Report 52 is populated for each Supplier Report 52 record with percentages obtained by summing the line items on time values of Summary Data 51 records in the corresponding subsets identified in step 5-2, multiplying each by 100, and dividing each by the corresponding totals obtained in step 5-7. Those skilled in the art will recognize that the number of line items or orders delivered on time may readily be reported as a percentage number, an absolute number, or both. Use of a percentage in a display report is desirable for facilitating subscribers to quickly compare on-time performance across several suppliers.

**[0034]** Those skilled in the art will recognize that process 50 represents just one example of a series of steps that might be used to convert Summary Data 51 into Supplier Report 52. Also, those skilled in the art will recognized that first executable code used to carry out a first step in process 50, might be the same code as second executable code used to carry out a second step in process 50.

13

[0037] **Figure 6** shows a sample reject report 60 that may be generated by the system of **Figure 1** using the decision flow illustrated in **Figure 7** and accompanying text. Report 60 includes table 61 and reports reject performance for a domestic supplier S3 during a reporting period. Column 61-c1 shows reject performance information for items in orders placed with supplier S3 by customer C2. Column 61-c2 shows reject performance items in orders placed by all customers to supplier S3. Row 61-r1 shows total lots in orders placed (at the intersection of row 61-r1 and column 61-c1, this reflects total lots in orders placed by customer C2 to supplier S3, and at the intersection for row 61-r2 and column 61-c2 this reflects total lots in orders placed by customer C2). Row 61-r2 shows the percentage of lots in row 61-r1 that are rejected due to the supplier. Row 61-r3 shows the percentage of lots in row 61-r1 that are rejected to the to customer.

[0038] **Figure 7** is a flow diagram illustrating predictive data elements and the predictions made by the system of **Figure 1** about the cause of rejects based on those predictive data elements in a system implementing an aspect of the present invention. The decision flow illustrated in **Figure 7** may be used to obtain a reject report such as reject report 60 of **Figure 6**. Customers and suppliers generally gather data that can be used in making a prediction about whether a reject was supplier caused or customer caused. Blocks 71a and 72-76 in **Figure 7** reflect predictive data elements that can be used by a supplier performance reporting system to make a prediction and report a reject as either supplier caused or customer caused.

[0039] Beginning at the top of the flow diagram, if the item was not returned, the result of block 71 is "no." If the item was not returned, but payment was less than the invoice, the system indicates that the order has, in a sense, been "rejected" in that the customer refused to pay the full amount. In such a case, the result of block 71a is "yes" and, as reflected by the arrow from block 71a to block 78, the system predicts and reports this rejection as supplier caused. If the payment was not less than the

invoice and the item was not returned, then the result of block 71a is "no" and the system reports the order as not rejected as indicated by the arrow from block 71a to block 71b.

[0040] If the order was returned, then the result of block 71 is "yes" as reflected by the arrow from block 71 to block 72. If the order was cancelled, the result of block 72 is "yes" and the reject is predicted and reported to be customer caused as indicated by the yes arrow from block 72 to block 77. If the answer is no, then, as illustrated by the arrow from block 72 to block 73, the system next considers whether or not the same item that was ordered was reshipped after the return. If the item was reshipped, then the result of block 73 is "yes" and the reject is predicted and reported to be supplier caused as indicated by the arrow from block 73 to block 78. If the result of block 73 is "no", then, as illustrated by the arrow from block 73 to block 74, the system next considers whether or not the delivery was late. If the delivery was late, the result of block 74 is "yes" and, as indicated by the arrow from block 74 to block 78, the reject is predicted and reported to be supplier caused. If the result of block 74 is "no", then, as illustrated by the arrow from block 74 to block 75, the system next considers whether or not there was a purchase order ("PO")/ invoice mismatch. If there was a PO/Invoice mismatch, then the result of block 75 is "yes" and, as indicated by the arrow from block 75 to block 78, the reject is predicted and reported as supplier caused. If the result of block 75 is "no", then, as illustrated by the arrow from block 75 to block 76, the system next considers whether or not an item shipped was defective. If an item shipped was defective, then the result of block 76 is "yes" and, as indicated by the arrow from block 76 to block 78, and the return is predicted and reported as supplier caused. If, however, the item shipped was not defective, then the result of block 76 is "no" and, as indicated by the arrow from block 76 to block 77, the return is predicted and reported as customer caused.

**[0041]** The order of blocks 72-76 may be varied. Note that if, for example, block 76 were not the last block, its "No" arrow would simply point to the next block rather than to block 77. If information is not available from either the supplier or customer to make a determination for one or more of the blocks 72-76, a "No" answer is delivered for those blocks with insufficient information and the remaining blocks are used to make a reject determination.

**[0042]** Executable code may instruct one or more computers to perform the processing steps illustrated in **Figure 7**. Those skilled in the art, many variations on executable code may be found that do not depart from the spirit and the scope of the present invention, but that, nevertheless, use predictive data elements to create reports analogous to the report illustrated in **Figure 6**, thereby allowing subscribers to evaluate reject performance in light of whether the rejects were supplier caused or customer caused.

**[0043]** Although particular embodiments have been described in detail, various modifications to the embodiments described herein may be made without departing from the spirit and scope of the present invention, thus, the invention is limited only by the appended claims.
